

CPSC-440 Computer System Architecture

MATLAB Review

Matlab

- Is a numerical computing environment and 4th generation programming language
- Developed by MathWorks, MATLAB allows matrix manipulations, plotting of functions and data, implementation of algorithms, creation of user interfaces, and interfacing with programs written in other languages, including C, C++, Java, and Fortran

Free Matlab for Students

Getting Started

 >> a = [12; 21] a = Define a matrix "a" computed its squar – "a times a" 1 2 1 Text in bold is what type in the comman window >> a*a Ordinary text is what the bold is what t	e you nd
Matlab outputs ans =	
5 4 4 5	

• To enter the matrix:

$$\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$$

• and store it in a variable "a", do this:

>> a = [1 2; 3 4];

• To redisplay the matrix, just type its name:

>> a

 Once you know how to enter and display matrices, it is easy to compute with them. First we will square the matrix "a":

• Now we'll try something a little harder. First we define a matrix b:

>> b = [1 2; 0 1];

- Then we compute the product ab:
 > a*b
- Finally, we compute the product in the other order:

- Notice that the two products are different
 Matrix multiplication is non-commutative
- Of course, we can also add matrices:

>> a + b

• Now let's store the result of this addition so that we can use it later:

>> s = a + b

• Matrices can sometimes be inverted:

>> inv(s)

• To check that this is correct, we compute the product of s and its inverse:

>> s * inv(s)

• The result is the unit, or identity matrix. We can also write the computation as

>> s/s

- We can also write
 >s\s
- which is the same as
 > inv(s) * s

• To see that these operations, left and right division, are really different, we do the following:

>> a/b >> a\b

Not all matrices can be inverted, or used as the denominator in matrix division:

>> c = [1 1; 1 1]; >> inv(c);

A matrix can be inverted if and only if its determinant is nonzero:

>> det(a) >> det(c)

Systems of Equations

• Now consider a linear equation

```
ax + by = p
```

```
cx + dy = q
```

• We can write this more compactly as

AX = B

- where the coefficient matrix A is
 - a b
 - c d
- the vector of unknowns is

```
Х
```

```
y
```

• and the vector on the right-hand side is

р

- q
- If A is invertible, X = (1/A)B, or, using Matlab notation, X = A\B. Let's try this out by solving ax = b with a as before and b = [1; 0]. Note that b is a column vector.

```
>> b = [ 1; 0 ]
>> a\b
```

Loops

- Loop Example
 - We regard x as representing (for example) the population state of an island
 - The first entry (1) gives the fraction of the population in the west half of the island, the second entry (0) give the fraction in the east half
 - The state of the population T units of time later is given by the rule y = ax
 - This expresses the fact that an individual in the west half stays put with probability 0.8 and moves east with probability 0.2 (note 0.8 + 0.2 = 1), and the fact that in individual in the east stays put with probability 0.9 and moves west with probability 0.1
 - Thus, successive population states can be predicted/computed by repeated matrix multiplication

```
>> a = [ 0.8 0.1; 0.2 0.9 ]
>> x = [ 1; 0 ]
>> for i = 1:20, x = a*x, end
```

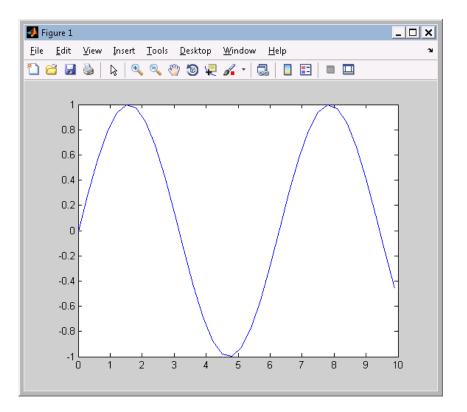

Graphing

Functions of One Variable

 To make a graph of y = sin(t) on the interval t = 0 to t = 10 we do the following:

- The command t = 0:.3:10; defines a vector with components ranging from 0 to 10 in steps of 0.3
- The y = sin(t); defines a vector whose components are sin(0), sin(0.3), sin(0.6), etc.
- Finally, plot(t,y) use the vector of t and y values to construct the graph

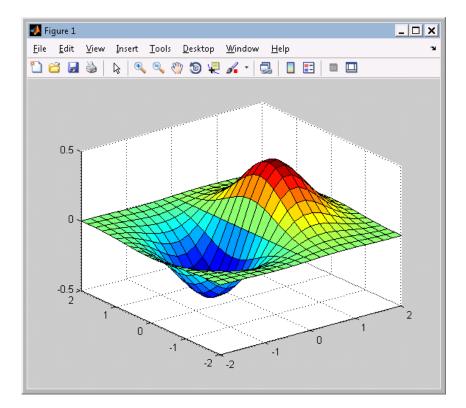

Graphing

Functions of Two Variable

• Here is how we graph the function $z(x, y) = xe^{(-x^2-y^2)}$

>> [x,y] = meshgrid(-2:.2:2, -2:.2:2); >> z = x .* exp(-x.^2 - y.^2); >> surf(x,y,z)

- The first command creates a matrix whose entries are the points of a grid in the square -2 <= x <= 2, -2 <= y <= 2
- The small squares which make up the grid are 0.2 units wide and 0.2 unit tall
- The second command creates a matrix whose entries are the values of the function z(x,y) at the grid points
- The third command uses this information to construct the graph
